Abstract. We investigate measures of complexity of function classes based on continuity moduli of Gaussian and Rademacher processes. For Gaussian processes, we obtain bounds on the continuity modulus on the convex hull of a function class in terms of the same quantity for the class itself. We also obtain new bounds on generalization error in terms of localized Rademacher complexities. This allows us to prove new results about generalization performance for convex hulls in terms of characteristics of the base class. As a byproduct, we obtain a simple proof of some of the known bounds on the entropy of convex hulls.

1 Introduction

Convex hulls of function classes have become of great interest in Machine Learning since the introduction of AdaBoost and other methods of combining classifiers. The most commonly used measure of complexity of convex hulls is based on covering numbers (or metric entropies). The first bound on the entropy of the convex hull of a set in a Hilbert space was obtained by Dudley [8] and later refined by Ball and Pajor [1] and a different proof was given independently by van der Vaart and Wellner [19]. These authors considered the case of polynomial growth of the covering numbers of the base class. Sharp bounds in the case of exponential growth of the covering numbers of the base class as well as extension of previously konwn results to the case of Banach spaces were obtained later [6,17,14,11,7].

In Machine Learning, however, the quantities of primary importance for determining the generalization performance are not the entropies themselves but rather localized Gaussian or Rademacher complexities of the function classes [12,2]. These quantities are closely related to continuity moduli of the corresponding stochastic processes.

Our main purpose in this paper is to provide an easy bound on the continuity modulus of stochastic processes like Rademacher or Gaussian processes on the convex hull of a class in terms of the continuity modulus on the class itself. We combine this result with some new bounds on the generalization error in function learning problems based on localized Rademacher complexities. This allows us to bound the generalization error for convex hulls in terms of characteristics of the base class.

In addition to this, we use the bounds on continuity moduli on convex hulls to give very simple proofs of some previously known results on the entropy of such classes.

2 Continuity Modulus on Convex Hulls

Let $\mathcal{F}$ be a subset of a Hilbert space $\mathcal{H}$ and W denote an isonormal Gaussian process defined on $\mathcal{H}$, that is a collection $(W(h))_{h \in \mathcal{H}}$ of Gaussian random variables indexed by $\mathcal{H}$ such that

$$\forall h \in \mathcal{H}, \ \mathbb{E}\left[W(h)\right] = 0 \ \text{ and } \ \forall h, h' \in \mathcal{H}, \ \mathbb{E}\left[W(h)W(h')\right] = \langle h, h' \rangle_{\mathcal{H}} \ .$$

We define the modulus of continuity of the process W as

$$\omega(\mathcal{F}, \delta) := \omega_{\mathcal{H}}(\mathcal{F}, \delta) = \mathbb{E}\left[\sup_{\substack{f, g \in \mathcal{F} \\ \|f-g\| \leq \delta}} |W(f) - W(g)|\right] \ .$$

Let $\mathcal{F}_\varepsilon$ denote a minimal ε-net of $\mathcal{F}$, i.e. a subset of $\mathcal{F}$ of minimal cardinality such that $\mathcal{F}$ is contained in the union of the balls of radius ε with centers in $\mathcal{F}_\varepsilon$. Let $\mathcal{F}^\varepsilon$ denote a maximal ε-separated subset of $\mathcal{F}$, i.e. a subset of $\mathcal{F}$ of maximal cardinality such that the distance between any two points in this subset is larger than or equal to ε. The ε-covering number of $\mathcal{F}$ is then defined as

$$N(\mathcal{F}, \varepsilon) := N_{\mathcal{H}}(\mathcal{F}, \varepsilon) = |\mathcal{F}_\varepsilon| \ ,$$

and the ε-entropy is $H(\mathcal{F}, \varepsilon) = \log N(\mathcal{F}, \varepsilon)$.

2.1 Main Result

Our main result relates the continuity modulus on the convex hull of a set $\mathcal{F}$ to the continuity modulus on this set.

Theorem 1. *We have for all $\delta \geq 0$*

$$\omega(\mathrm{conv}(\mathcal{F}), \delta) \leq \inf_\varepsilon \left(2\omega(\mathcal{F}, \varepsilon) + \delta\sqrt{N(\mathcal{F}, \varepsilon)}\right) \ .$$

Proof. Let $\varepsilon > 0$, L be the linear span of $\mathcal{F}_\varepsilon$ and Π_L be the orthogonal projection on L. We have for all $f \in \mathcal{F}$,

$$f = \Pi_L(f) + \Pi_{L^\perp}(f) \ .$$

$$\omega(\mathrm{conv}(\mathcal{F}), \delta) \leq \mathbb{E}\left[\sup_{\substack{f,g \in \mathrm{conv}(\mathcal{F}) \\ \|f-g\| \leq \delta}} |W(\Pi_L f) - W(\Pi_L g)|\right]$$

$$+ \mathbb{E}\left[\sup_{\substack{f,g \in \mathrm{conv}(\mathcal{F}) \\ \|f-g\| \leq \delta}} |W(\Pi_{L^\perp} f) - W(\Pi_{L^\perp} g)|\right].$$

Now since for any orthogonal projection Π, $\|\Pi(f) - \Pi(g)\| \leq \|f - g\|$ we have

$$\omega(\mathrm{conv}(\mathcal{F}), \delta) \leq \omega(\Pi_L \mathrm{conv}(\mathcal{F}), \delta) + \omega(\Pi_{L^\perp} \mathrm{conv}(\mathcal{F}), \delta).$$

Moreover, we have $\Pi \mathrm{conv}(\mathcal{F}) = \mathrm{conv}(\Pi\mathcal{F})$ by linearity of the orthogonal projection so that

$$\omega(\mathrm{conv}(\mathcal{F}), \delta) \leq \omega(\mathrm{conv}(\Pi_L \mathcal{F}), \delta) + \omega(\mathrm{conv}(\Pi_{L^\perp} \mathcal{F}), \delta).$$

This gives the first inequality. Next we have

$$\omega(\Pi_L \mathrm{conv}(\mathcal{F}), \delta) \leq \omega(L, \delta),$$

and by linearity of W,

$$\omega(L, \delta) = \mathbb{E}\left[\sup_{\substack{f \in L \\ \|f\| \leq \delta}} |W(f)|\right] \leq \delta \mathbb{E}\left[\sup_{\substack{\|y\|_{\mathbb{R}^d} \leq 1 \\ y \in \mathbb{R}^d}} \langle Z, y \rangle\right],$$

where Z is a standard normal vector in $\mathbb{R}^d$ (with $d = \dim L$ and $\|\cdot\|_{\mathbb{R}^d}$ the euclidean norm in $\mathbb{R}^d$). This gives

$$\omega(L, \delta) \leq \delta \mathbb{E}\left[\|Z\|_{\mathbb{R}^d}\right] \leq \delta \sqrt{\dim L} \leq \delta \sqrt{N(\mathcal{F}, \varepsilon)}.$$

We also get

$$\omega(\Pi_{L^\perp} \mathrm{conv}(\mathcal{F}), \delta) \leq 2\mathbb{E}\left[\sup_{f \in \mathrm{conv}(\mathcal{F})} |W(\Pi_{L^\perp} f)|\right].$$

Since $\Pi_{L^\perp}$ is linear, the supremum is attained at elements of $\mathcal{F}$, that is

$$\omega(\Pi_{L^\perp} \mathrm{conv}(\mathcal{F}), \delta) \leq 2\mathbb{E}\left[\sup_{f \in \mathcal{F}} |W(\Pi_{L^\perp} f)|\right].$$

Now for each $f \in \mathcal{F}$, let g be the closest point to f in $\mathcal{F}_\varepsilon$. Then we have $\|f - g\| \leq \varepsilon$ and $g \in L \cap \mathcal{F}$ so that $\Pi_{L^\perp} g = 0$ and thus

$$\omega(\Pi_{L^\perp} \mathrm{conv}(\mathcal{F}), \delta) \leq 2\mathbb{E}\left[\sup_{\substack{f,g \in \mathcal{F} \\ \|f-g\| \leq \varepsilon}} |W(\Pi_{L^\perp} f) - W(\Pi_{L^\perp} g)|\right].$$

Now since $\Pi_{L^{\perp}}$ is a contraction, using Slepian's lemma (see [13], Theorem 3.15 page 78) we get

$$\omega(\Pi_{L^{\perp}}\operatorname{conv}(\mathcal{F}),\delta) \leq 2\mathbb{E}\left[\sup_{\substack{f,g\in\mathcal{F}\\ \|f-g\|\leq\varepsilon}} |W(f)-W(g)|\right] = 2\omega(\mathcal{F},\varepsilon)\,.$$

This concludes the proof. $\qquad\square$

Note that Theorem 1 allows us to give a positive answer to a question raised by Dudley [10]. Indeed, we can prove that the convex hull of a uniformly Donsker class is uniformly Donsker. Due to lack of space, we do not give the details here.

2.2 Examples

As an application of Theorem 1, we will derive bounds on the continuity modulus of convex hulls of classes for which we know the rate of growth of the entropy.

By Dudley's entropy bound (see [13], Theorem 11.17, page 321) we have

$$\omega(\mathcal{F},\varepsilon) \leq K \int_0^\varepsilon H^{1/2}(\mathcal{F},u)\,du\,.$$

We will also use below the following version of this result (that easily follows from Dudley's chaining argument and is well known)

$$\omega(\mathcal{F}^\delta,\varepsilon) \leq K \int_\delta^\varepsilon H^{1/2}(\mathcal{F}^\delta,u)\,du\,,$$

for all $\varepsilon > \delta$.

We first consider the case when the entropy of the base class grows logarithmically.

Example 1. If for all $\varepsilon > 0$,

$$N(\mathcal{F},\varepsilon) \leq K\varepsilon^{-V}\,,$$

then for all $\delta > 0$,

$$\omega(\operatorname{conv}(\mathcal{F}),\delta) \leq K\delta^{2/(2+V)}\log^{V/(2+V)}\delta^{-1}\,.$$

Proof. We have from Theorem 1,

$$\omega(\operatorname{conv}(\mathcal{F}),\delta) \leq \inf_\varepsilon \left(K\int_0^\varepsilon \log^{1/2} u^{-1}du + \delta\varepsilon^{-V/2}\right)$$

$$\leq \inf_\varepsilon \left(K\varepsilon\log^{1/2}\varepsilon^{-1} + \delta\varepsilon^{-V/2}\right)\,.$$

Choosing

$$\varepsilon = \delta^{2V/(2+V)}\log^{2V/(2+V)}\delta^{-1}\,,$$

we obtain for $\delta \leq 1$,

$$\omega(\operatorname{conv}(\mathcal{F}),\delta) \leq K\delta^{2/(2+V)}\log^{V/(2+V)}\delta^{-1}\,.$$

$\qquad\square$

Although the main term in the above bound is correct, we obtain a superfluous logarithm. This logarithm can be removed if one uses directly the entropy integral in combination with results on the entropy of the convex hull of such classes [1,19,17]. At the moment of this writing, we do not know a simple proof of this fact that does not rely upon the bounds on the entropy of convex hulls.

Now we consider the case when the entropy of the base class has polynomial growth. In this case, we shall distinguish several situations: when the exponent is larger than 2, the class is no longer pre-Gaussian which means that the continuity modulus is unbounded. However, it is possible to study the continuity modulus of a restricted class. Here we consider the convex hull of a δ-separated subset of the base class, for which the continuity modulus is bounded when computed at a scale proportional to δ.

Example 2. If for all $\varepsilon > 0$,

$$H(\mathcal{F}, \varepsilon) \leq K\varepsilon^{-V},$$

then for all $\delta > 0$, for $0 < V < 2$,

$$\omega(\mathrm{conv}(\mathcal{F}), \delta) \leq K \log^{1/2 - 1/V} \delta^{-1},$$

for $V = 2$,

$$\omega(\mathrm{conv}(\mathcal{F}^{\delta/4}), \delta) \leq K \log \delta^{-1},$$

and for $V > 2$,

$$\omega(\mathrm{conv}(\mathcal{F}^{\delta/4}), \delta) \leq K\delta^{1-V/2}.$$

Proof. We have from Theorem 1, for $\epsilon > \delta/4$,

$$\omega(\mathrm{conv}(\mathcal{F}^{\delta/4}), \delta) \leq \inf_{\varepsilon} \left(K \int_{\delta/4}^{\varepsilon} u^{-V/2} du + \delta \exp(K\varepsilon^{-V}/2) \right).$$

For $0 < V < 2$, this gives

$$\omega(\mathrm{conv}(\mathcal{F}), \delta) \leq \inf_{\varepsilon} \left(K\varepsilon^{(2-V)/2} + \delta \exp(K\varepsilon^{-V}/2) \right).$$

Choosing

$$\varepsilon = K^{1/V} \log^{-1/V} \delta^{-1},$$

we obtain for δ small enough

$$\omega(\mathrm{conv}(\mathcal{F}), \delta) \leq K \log^{(V-2)/2V} \delta^{-1}.$$

For $V = 2$, we get

$$\omega(\mathrm{conv}(\mathcal{F}^{\delta/4}), \delta) \leq \inf_{\varepsilon} \left(K \log \frac{4\epsilon}{\delta} + \delta \exp(K\varepsilon^{-2}/2) \right).$$

Taking $\epsilon = 1/4$ we get for δ small enough

$$\omega(\mathrm{conv}(\mathcal{F}^{\delta/4}), \delta) \leq K \log \delta^{-1}.$$

For $V > 2$, we get

$$\omega(\mathrm{conv}(\mathcal{F}^{\delta/4}), \delta) \le \inf_\varepsilon \left(K\delta^{(2-V)/2} - \varepsilon^{(2-V)/2} + \delta \exp(K\varepsilon^{-2}/2) \right).$$

Taking $\varepsilon \to \infty$, we obtain

$$\omega(\mathrm{conv}(\mathcal{F}^{\delta/4}), \delta) \le K\delta^{(2-V)/2}.$$

$\square$

3 Generalization Error Bounds

3.1 Results

We begin this section with a general bound that relates the error of the function minimizing the empirical risk to a local measure of complexity of the class which is the same in spirit as the bound in [12].

Let $(S, \mathcal{A})$ be a measurable space and let $X_1, \ldots, X_n$ be n i.i.d. random variables in this space with common distribution P. P_n will denote the empirical measure based on the sample

$$P_n = \frac{1}{n} \sum_{i=1}^{n} \delta_{X_i}.$$

In what follows, $\mathcal{H} = L_2(P_n)$ and we are using the notations of Section 2.

We consider a class $\mathcal{F}$ of measurable functions defined on S with values in $[0, 1]$. We assume in what follows that $\mathcal{F}$ also satisfies standard measurability conditions used in the theory of empirical processes as in [9,19].

We define

$$R_n(f) := \frac{1}{n} \sum_{i=1}^{n} \varepsilon_i f(X_i),$$

and let ψ_n be an increasing concave (possibly data-dependent random) function with $\psi_n(0) = 0$ such that

$$\mathbb{E}_\varepsilon \left[\sup_{P_n f \le r} |R_n(f)| \right] \le \psi_n(\sqrt{r}), \ \forall r \ge 0.$$

Let $\hat{r}_n$ be the largest solution of the equation

$$r = \psi_n(\sqrt{r}). \tag{1}$$

The solution $\hat{r}_n$ of (1) gives what is usually called zero error rate for the class $\mathcal{F}$[12], i.e. the bound for Pf given that $P_n f = 0$.

The bounds we obtain below are data-dependent and they do not require any structural assumptions on the class (such as VC conditions or entropy conditions). Note that $\hat{r}_n$ is determined only by the restriction of the class $\mathcal{F}$ to the sample $(X_1, \ldots, X_n)$.

Theorem 2. *If ψ_n is a non-decreasing concave function and $\psi_n(0) = 0$ then there exists $K > 0$ such that with probability at least $1 - 2e^{-t}$ for all $f \in \mathcal{F}$*

$$Pf \leq K \left(P_n f + \hat{r}_n + \frac{t + \log\log n}{n} \right) . \tag{2}$$

It is most common to estimate the expectation of Rademacher processes via entropy integral (Theorem 2.2.4 in [19]):

$$\mathbb{E}_\varepsilon \left[\sup_{P_n f \leq \delta} |R_n(f)| \right] \leq \frac{4\sqrt{3}}{\sqrt{n}} \int_0^{\sqrt{\delta}/2} H^{1/2}(\mathcal{F}, u) du ,$$

which means one can choose $\psi_n(\delta)$ as the right hand side of the above bound. This approach was used for instance in [12].

Our goal here will be to apply the bound of Theorem 2 to the function learning problem in the convex hull of a given class.

Let $\mathcal{G}$ be a class of measurable functions from S into $[0, 1]$. Let $g_0 \in \mathrm{conv}(\mathcal{G})$ be an unknown target function. The goal is to learn g_0 based on the data $(X_1, g_0(X_1)), \ldots, (X_n, g_0(X_n))$. We introduce $\hat{g}_n$ defined as

$$\hat{g}_n := \arg\min_{g \in \mathrm{conv}(\mathcal{G})} P_n |g - g_0| ,$$

which in principle can be computed from the data.

We introduce the function $\psi_n(\mathcal{G}, \delta)$ defined as

$$\psi_n(\mathcal{G}, \delta) := \sqrt{\frac{\pi}{2n}} \inf_{\varepsilon > 0} \left(\omega(\mathcal{G}, \varepsilon) + \delta \sqrt{N(\mathcal{G}, \varepsilon)} \right) .$$

Corollary 1. *Let $\hat{r}_n(\mathcal{G})$ be the largest solution of the equation*

$$r = \psi_n(\mathcal{G}, \sqrt{r}) .$$

Then there exists $K > 0$ such that for all $g_0 \in \mathrm{conv}(\mathcal{G})$ the following inequality holds with probability at least $1 - 2e^{-t}$

$$P|\hat{g}_n - g_0| \leq K \left(\hat{r}_n(\mathcal{G}) + \frac{t + \log\log n}{n} \right) .$$

Proof. Let $\mathcal{F} = \{|g - g_0| : g \in \mathrm{conv}(\mathcal{G})\}$. Note that $\psi_n(\mathcal{G}, \delta)$ is concave non-decreasing (as the infimum of linear functions) and $\psi_n(\mathcal{G}, 0) = 0$, it can thus be used in Theorem 2. We obtain (using bound (4.8) on page 97 of [13])

$$\mathbb{E} \left[\sup_{\substack{f \in \mathcal{F} \\ P_n f \leq r}} |R_n(f)| \right] \leq \sqrt{\frac{\pi}{2n}} \mathbb{E} \left[\sup_{\substack{f \in \mathcal{F} \\ P_n f \leq r}} |W_{P_n}(f)| \right]$$

$$\leq \sqrt{\frac{\pi}{2n}} \mathbb{E} \left[\sup_{\substack{f \in \mathcal{F} \\ (P_n f^2)^{1/2} \leq \sqrt{r}}} |W_{P_n}(f)| \right]$$

$$\leq \sqrt{\frac{\pi}{2n}} \omega(\mathrm{conv}\,\mathcal{G}, \sqrt{r}) \leq \psi_n(\mathcal{G}, \sqrt{r}) ,$$

where in the last step we used Theorem 1. To complete the proof, it is enough to notice that $P_n|\hat{g}_n - g_0| = 0$ (since $g_0 \in \text{conv}(\mathcal{G})$) and to use the bound of Theorem 2. $\qquad\square$

A simple application of the above corollary in combination with the bounds of examples 1 and 2 give, for instance, the following rates. If the covering numbers of the base class grow polynomially, i.e. for some $V > 0$,

$$N(\mathcal{G}, \varepsilon) \leq K\varepsilon^{-V},$$

then we obtain $\hat{r}_n$ of the order of

$$n^{-\frac{1}{2}\frac{2+V}{1+V}}.$$

This can be compared with the main result in [18]. If the entropy is polynomial with exponent $0 < V < 2$, $\hat{r}_n$ is of the order of

$$n^{-\frac{1}{2}}\log^{1/2-1/V} n.$$

3.2 Additional Proofs

Our main goal in this section is to prove Theorem 2.

Denote

$$l(\delta) = 2\log\left(\frac{\pi}{\sqrt{3}}\log_2\frac{2}{\delta}\right)$$

and define $U(\delta)$ as the largest solution of the equation

$$U = \delta + 8\mathbb{E}_\varepsilon\left[\sup_{P_n f \leq U}|R_n(f)|\right] + \left(\frac{2\delta(t + l(\delta))}{n}\right)^{1/2} + \frac{10(t + l(\delta))}{3n} \qquad (3)$$

while $r(\delta)$ is the largest solution of the equation

$$r = \delta + 8\mathbb{E}_\varepsilon\left[\sup_{P_n f \leq U(2r)}|R_n(f)|\right] + \left(\frac{4r(t + l(2r))}{n}\right)^{1/2} + \frac{10(t + l(2r))}{3n}. \qquad (4)$$

Notice that the construction of $r(\delta)$ depends only on the sample $(X_1, \ldots, X_n)$ and the restriction of the class $\mathcal{F}$ to the sample.

Theorem 3. *With probability at least $1 - 2e^{-t}$ for all $f \in \mathcal{F}$*

$$Pf \leq r(P_n f). \qquad (5)$$

Proof. We define $\delta_k = 2^{-k}$ for $k \geq 0$, and consider a sequence of classes

$$\mathcal{F}_k = \{f \in \mathcal{F} : \delta_{k+1} < Pf \leq \delta_k\}.$$

If we denote

$$R_k = \mathbb{E}_\varepsilon\left[\sup_{\mathcal{F}_k}|R_n(f)|\right],$$

then the symmetrization inequality implies that

$$\mathbb{E}\left[\sup_{\mathcal{F}_k}|P_nf - Pf|\right] \leq 2\mathbb{E}\left[R_k\right],$$

which in combination with Theorem 3 in [4] (with $P(f-Pf)^2 \leq Pf^2 \leq Pf \leq \delta_k$) implies that with probability at least $1 - e^{-t}$ for all $f \in \mathcal{F}_k$

$$|P_nf - Pf| \leq 4\mathbb{E}\left[R_k\right] + \left(\frac{2\delta_k t}{n}\right)^{1/2} + \frac{4t}{3n}.$$

Theorem 16 in [3] gives that with probability at least $1 - e^{-t}$

$$\mathbb{E}\left[R_k\right] \leq \left(\left(\frac{t}{2n}\right)^{1/2} + \left(\frac{t}{2n} + R_k\right)^{1/2}\right)^2 \leq \frac{2t}{n} + 2R_k.$$

Therefore, with probability at least $1 - 2e^{-t}$ for all $f \in \mathcal{F}_k$

$$|P_nf - Pf| \leq 8R_k + \left(\frac{2\delta_k t}{n}\right)^{1/2} + \frac{10t}{3n}.$$

Finally, replacing t by $t + l(\delta_k)$ and applying the union bound we get that with probability at least $1 - 2e^{-t}$ for all $k \geq 0$ and for all $f \in \mathcal{F}_k$

$$|P_nf - Pf| \leq 8R_k + \left(\frac{2\delta_k(t + l(\delta_k))}{n}\right)^{1/2} + \frac{10(t + l(\delta_k))}{3n}. \qquad (6)$$

If we denote

$$U_k = \delta_k + 8R_k + \left(\frac{2\delta_k(t + l(\delta_k))}{n}\right)^{1/2} + \frac{10(t + l(\delta_k))}{3n}$$

then on this event for any fixed k and for all $f \in \mathcal{F}_k$, $P_nf \leq U_k$ and, hence,

$$R_k \leq \mathbb{E}_\varepsilon\left[\sup_{P_nf \leq U_k}|R_n(f)|\right]$$

which can be rewritten in terms of U_k as

$$U_k \leq \delta_k + 8\mathbb{E}_\varepsilon\left[\sup_{P_nf \leq U_k}|R_n(f)|\right] + \left(\frac{2\delta_k(t + l(\delta_k))}{n}\right)^{1/2} + \frac{10(t + l(\delta_k))}{3n}.$$

This means that $U_k \leq U(\delta_k)$, where $U(\delta)$ is defined in (3). Finally, (6) implies that for all k and $f \in \mathcal{F}_k$

$$Pf \leq P_nf + 8\mathbb{E}_\varepsilon\left[\sup_{P_nf \leq U(\delta_k)}|R_n(f)|\right] + \left(\frac{2\delta_k(t + l(\delta_k))}{n}\right)^{1/2} + \frac{10(t + l(\delta_k))}{3n}.$$

If $f \in \mathcal{F}_k$ then $\delta_k \leq 2Pf$, which proves the theorem. $\qquad \square$

Notice that if we replace the right-hand sides of (3) and (4) by upper bounds, we only increase the value of the solutions and the theorem remains true for these new solutions. Moreover, since the solution of (4) is necessarily larger than $1/n$, it is enough to consider (3) only for $\delta > 1/n$. So assuming that we have the bound

$$\mathbb{E}_\varepsilon \left[\sup_{P_n f \leq r} |R_n(f)| \right] \leq \psi_n(\sqrt{r}),$$

we can replace (using that $2\sqrt{ab} \leq a + b$) (3) and (4) by

$$U = K_1 \left(\delta + \psi_n(\sqrt{U}) + r_0 \right), \tag{7}$$

$$r = \delta + K_2 \left(\psi_n(\sqrt{U^e(2r)}) + \sqrt{rr_0} + r_0 \right). \tag{8}$$

where $r_0 = (t + \log\log n)/n$. The solutions of those equations are denoted respectively $U_1(\delta)$ and $r_1(\delta)$.

Proof of Theorem 2. Let $\alpha < 1$ and consider k non-negative functions ϕ_i satisfying one of the following conditions

$$\forall x > 0, \ \forall C > 1, \ \phi_i(Cx) \leq C^\alpha \phi_i(x), \tag{9}$$

or

$$\phi_i(x) \text{ is non-increasing for } x > 0. \tag{10}$$

Define now for each $i = 1, \ldots, k$ u_i as the largest solution of the equation

$$u = \phi_i(u),$$

(assuming the existence of the solutions).
Note that from the conditions (9) or (10), we obtain for all $c > 0$ and all $C > 1$

$$\phi_i(C(u_i + c)) \leq C^\alpha(u_i + c). \tag{11}$$

We thus deduce that the largest solution u^* of the equation

$$u = \sum_{i=1}^k \phi_i(u),$$

satisfies $u^* \leq C \sum_{i=1}^k u_i$ for some large enough C.
It is easy to see that the right-hand side of (7) is a sum of functions satisfying (11). Indeed, we have by the concavity of ψ_n (and $\psi_n(0) = 0$) and the definition of $\hat{r}_n$,

$$\psi_n(\sqrt{C(\hat{r}_n + c)}) \leq \sqrt{C}\psi_n(\sqrt{\hat{r}_n + c}) \leq \sqrt{C}(\hat{r}_n + c).$$

The above reasoning thus proves that $U_1(\delta) \leq K(\delta + \hat{r}_n + r_0))$.

We can thus replace equation (8) by the following whose solution $r_2(\delta)$ will upper bound $r_1(\delta)$:

$$r = \delta + K_1 \left(\psi_n(\sqrt{K_2(r + \hat{r}_n + r_0)}) + \sqrt{rr_0} + r_0 \right) .$$

Once again we can check that the righ-hand side is a sum of functions satisfying (11). The same reasoning as before proves that

$$r(\delta) \leq r_2(\delta) \leq K \left(\delta + \hat{r}_n + r_0 \right) ,$$

which finishes the proof. $\qquad\square$

4 Entropy of Convex Hulls

4.1 Relating Entropy With Continuity Modulus

By Sudakov's minoration (see [13], Theorem 3.18, page 80) we have

$$\sup_{\varepsilon > 0} \varepsilon H^{1/2}(\mathcal{F}, \varepsilon) \leq K \mathbb{E} \left[\sup_{f \in \mathcal{F}} |W(f)| \right] .$$

Let $B(f, \delta)$ be the ball centered in f of radius δ. We define

$$H(\mathcal{F}, \delta, \varepsilon) := \sup_{f \in \mathcal{F}} H(B(f, \delta) \cap \mathcal{F}, \varepsilon) .$$

The following lemma relates the entropy of $\mathcal{F}$ with the modulus of continuity of the process W. This type of bound is well known (see e.g. [15]) but we give the proof for completeness.

Lemma 1. *Assume $\mathcal{F}$ is of diameter 1. For all integer k we have*

$$H^{1/2}(\mathcal{F}, 2^{-k}) \leq K \sum_{i=0}^{k} 2^i \omega(\mathcal{F}, 2^{1-i}) .$$

This can also be written

$$H^{1/2}(\mathcal{F}, \delta) \leq K \int_{\delta}^{1} u^{-2} \omega(\mathcal{F}, u) \, du .$$

Proof. We have

$$\omega(\mathcal{F}, \delta) = \mathbb{E} \left[\sup_{\substack{f, g \in \mathcal{F} \\ \|f - g\| \leq \delta}} |W(f) - W(g)| \right]$$

$$\geq \sup_{f \in \mathcal{F}} \mathbb{E} \left[\sup_{g \in B(f, \delta) \cap \mathcal{F}} |W(f) - W(g)| \right]$$

$$\geq \sup_{f \in \mathcal{F}} \sup_{\varepsilon > 0} \varepsilon H^{1/2}(B(f, \delta) \cap \mathcal{F}, \varepsilon) ,$$

so that we obtain

$$\frac{\delta}{2} H^{1/2}(\mathcal{F}, \delta, \frac{\delta}{2}) \le K\omega(\mathcal{F}, \delta) \,.$$

Notice that we can construct a 2^{-k} covering of $\mathcal{F}$ by covering $\mathcal{F}$ by $N(\mathcal{F}, 1)$ balls of radius 1 and then covering the intersection of each of these balls with $\mathcal{F}$ with $N(B(f, 1) \cap \mathcal{F}, 1/2)$ balls of radius $1/2$ and so on. We thus have

$$N(\mathcal{F}, 2^{-k}) \le \prod_{i=0}^{k} \sup_{f \in \mathcal{F}} N(B(f, 2^{1-i}) \cap \mathcal{F}, 2^{-i}) \,.$$

Hence

$$H(\mathcal{F}, 2^{-k}) \le \sum_{i=0}^{k} H(\mathcal{F}, 2^{1-i}, 2^{-i}) \,.$$

We thus have

$$H^{1/2}(\mathcal{F}, 2^{-k}) \le \sum_{i=0}^{k} H^{1/2}(\mathcal{F}, 2^{1-i}, 2^{-i}) \le K \sum_{i=0}^{k} 2^i \omega(\mathcal{F}, 2^{1-i}) \,,$$

which concludes the proof. $\qquad\square$

Next we present a modification of the previous lemma that can be applied to δ-separated subsets.

Lemma 2. *Assume $\mathcal{F}$ is of diameter 1. For all integer k we have*

$$H^{1/2}(\mathcal{F}, 2^{-k}) \le K \sum_{i=0}^{k} 2^i \omega(\mathcal{F}^{2^{-i-1}}, 2^{2-i}) \,.$$

Proof. Notice that for $f \in \mathcal{F}$, there exists $f' \in \mathcal{F}^{\delta/4}$ such that

$$B(f, \delta) \cap \mathcal{F} \subset B(f', \delta + \delta/4) \cap \mathcal{F} \,.$$

Moreover, since a maximal δ-separated set is a δ-net,

$$N(\mathcal{F}, \delta) \le |N^\delta| = N(\mathcal{F}^\delta, \delta/2) \,,$$

since for a δ-separated set A we have $N(A, \delta/2) = |A|$.
Let's prove that we have for any γ,

$$\left| (B(f, \gamma) \cup \mathcal{F})^{\delta/2} \right| \le \left| B(f, \gamma + \delta/4) \cup \mathcal{F}^{\delta/4} \right| \,.$$

Indeed, since the points in $\mathcal{F}^{\delta/4}$ form a $\delta/4$ cover of $\mathcal{F}$, all the points in $(B(f, \gamma) \cup \mathcal{F})^{\delta/2}$ are at distance less than $\delta/4$ of one and only one point of $\mathcal{F}^{\delta/4}$ (the unicity comes from the fact that they are $\delta/2$ separated). We can thus establish an injection from points in $(B(f, \gamma) \cup \mathcal{F})^{\delta/2}$ to corresponding points

in $\mathcal{F}^{\delta/4}$ and the image of this injection is included in $B(f, \gamma + \delta/4)$ since the image points are within distance $\delta/4$ of points in $B(f, \gamma)$.

Now we obtain

$$N((B(f', \delta + \delta/4) \cup \mathcal{F})^{\delta/2}, \delta/4) \leq N(B(f', 3\delta/2) \cup \mathcal{F}^{\delta/4}, \delta/8).$$

We thus have

$$\begin{aligned}
N(B(f, \delta) \cup \mathcal{F}, \delta/2) &\leq N(B(f', \delta + \delta/4) \cup \mathcal{F}, \delta/2) \\
&\leq N((B(f', \delta + \delta/4) \cup \mathcal{F})^{\delta/2}, \delta/4) \\
&\leq N(B(f', 3\delta/2) \cup \mathcal{F}^{\delta/4}, \delta/8).
\end{aligned}$$

This gives

$$\begin{aligned}
\sup_{f \in \mathcal{F}} N(B(f, \delta) \cap \mathcal{F}, \delta/2) &\leq \sup_{f \in \mathcal{F}^{\delta/4}} N(B(f, 3\delta/2) \cap \mathcal{F}^{\delta/4}, \delta/8) \\
&= N(\mathcal{F}^{\delta/4}, 3\delta/2, \delta/8).
\end{aligned}$$

Hence

$$H(\mathcal{F}, \delta, \delta/2) \leq H(\mathcal{F}^{\delta/4}, 3\delta/2, \delta/8).$$

By the same argument as in previous Lemma we obtain

$$\frac{\delta}{8} H^{1/2}(\mathcal{F}^{\delta/4}, 3\delta/2, \delta/8) \leq K\omega(\mathcal{F}^{\delta/4}, 3\delta/2).$$

$\square$

4.2 Applications

Example 3. If for all $\varepsilon > 0$,

$$N(\mathcal{F}, \varepsilon) \leq \varepsilon^{-V},$$

then for all $\varepsilon > 0$,

$$H(\mathrm{conv}(\mathcal{F}), \varepsilon) \leq \varepsilon^{-2V/(2+V)} \log^{2V/(2+V)} \varepsilon^{-1}.$$

Proof. Recall from Example 1 that

$$\omega(\mathrm{conv}(\mathcal{F}), \delta) \leq K\delta^{2/(2+V)} \log^{V/(2+V)} \delta^{-1}.$$

Now, using Lemma 1 we get

$$\begin{aligned}
H^{1/2}(\mathrm{conv}(\mathcal{F}), 2^{-k}) &\leq K \sum_{i=0}^{k} 2^i 2^{2(1-i)/(2+V)} (i-1)^{V/(2+V)} \\
&= K \sum_{i=0}^{k} (2^{V/(2+V)})^i (i-1)^{V/(2+V)}.
\end{aligned}$$

We check that in the above sum, the i-th term is always larger than twice the $i - 1$-th term (for $i \geq 2$) so that we can upper bound the sum by the last term,

$$H^{1/2}(\mathcal{F}, 2^{-k}) \leq K(2^{V/(2+V)})^k (k-1)^{V/(2+V)},$$

hence, using $\varepsilon = 2^{-k}$, we get the result. $\qquad \square$

Note that the result we obtain contains an extra logarithmic factor compared to the optimal bound [19,17].

Example 4. If for all $\varepsilon > 0$,

$$H(\mathcal{F}, \varepsilon) \leq \varepsilon^{-V},$$

then for all $\varepsilon > 0$, for $0 < V < 2$,

$$H(\text{conv}(\mathcal{F}), \varepsilon) \leq \varepsilon^{-2} \log^{1-V/2} \varepsilon^{-1},$$

for $V = 2$,

$$H(\text{conv}(\mathcal{F}), \varepsilon) \leq \varepsilon^{-2} \log^2 \varepsilon^{-1},$$

and for $V > 2$,

$$H(\text{conv}(\mathcal{F}), \varepsilon) \leq \varepsilon^{-V}.$$

Proof. The proof is similar to the previous one. $\qquad \square$

In this example, all the bounds are known to be sharp [6,11].
